1 Weighing of Components

Summary

Some production areas require components to be weighed using scales and to provide them for further production processes.

Usage

The function is always used when the user prepares charges using the relevant material quantities. To save time, users often weigh several charges at once.

The logical process and posting are described here.

Prerequisite/configuration

The configuration is described here.

Weighing components

Components for a charge are weighed by the AIP dialog A_VBRKOMP.

If the terminal is offline, only a limited number of posting functions is provided based on the available data. If the terminal is offline, errors are not displayed e.g. if posting failed on the server.

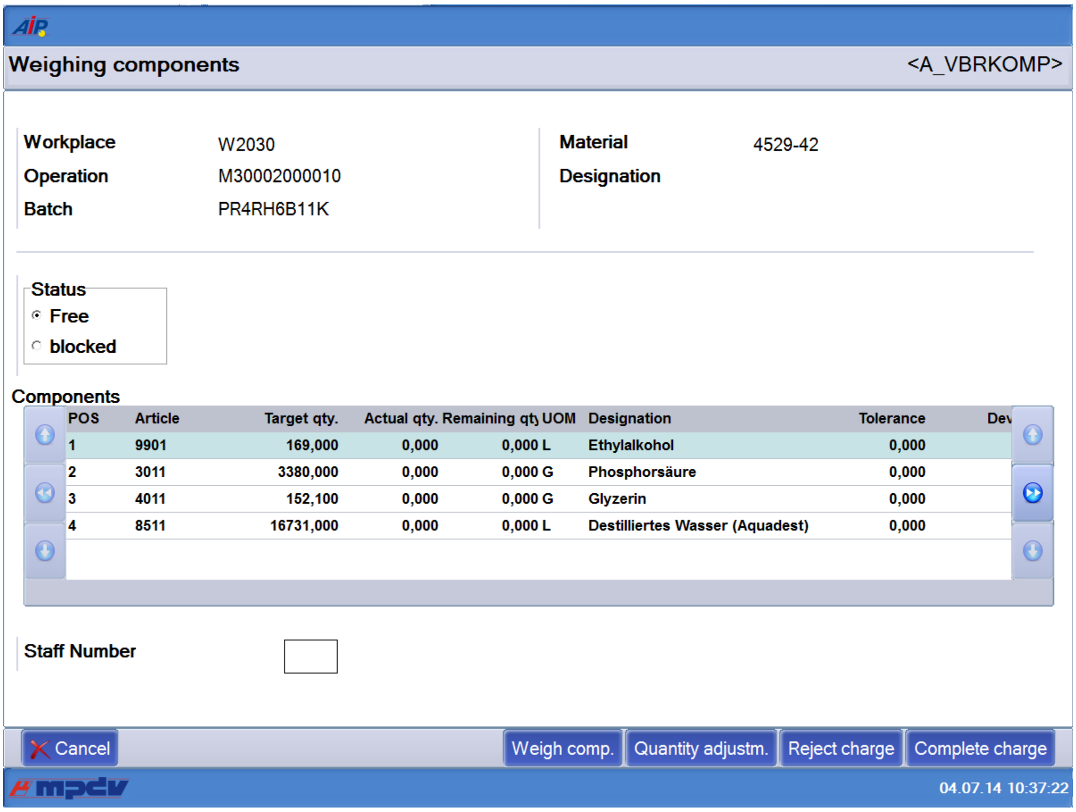
The "weighing" function at the terminal provides a list of required input materials (discrete material components). The component-related data collection can be opened from this list.

Once the operation to be weighed has been logged on, the "weighing components" dialog can be started by the "weigh" function key from the toolbar of the basic screen of the terminal. After opening the dialog, the terminal automatically generates a new batch for the order. This is presented as batch in the following dialog.

Please note: The dialog only opens if "discrete" material components (consumption type = D) exist for the running operation.

The actual weighing process of the relevant components is performed by the "weigh charge" function in a detailed dialog (see below).

Dialog



Workplace

Weighing workplace to which the operation to be weighed is logged on.

Operation

Weighing order/operation

Batch

Batch number for the charge that is currently to be produced.

Material

Material number for the charge that is currently to be produced.

Status

Batch status for the charge that is currently to be produced after weighing. This can be:

- Free
- Locked

Staff badge number

The user's staff badge number.

Components list

The component list shows all components of the currently registered weighing operation that are relevant for the charge to be produced. These details for the component are displayed to perform weighing:

- Article number (material number of the component from the component list)
- Target quantity
- Actual quantity (quantity entered upon weighing, at first 0,000)
- Remaining quantity (computed remaining quantity after weighing, at first 0,000)
- Designation (component name from the component list)
- Tolerance (calculated, admissible tolerance of the component/component list)
- Deviation (calculated, admissible deviation of the component/component list)

Procedure:

The user selects the first component that is to be weighed and starts weighing.

- The relevant component row is highlighted in **green** if the component is within the variance tolerance (at the component, percentage).
- Materials falling short of the variance tolerance are highlighted in **red.**
- Materials the weighing result of which exceeds the variance tolerance but is still within the tolerances of quantity adjustment (of the component) are highlighted in **blue.**
- The row is shown in black font, provided that the component has not yet been weighed.
- If the weight value is beyond the variance tolerance but within the tolerance of quantity adjustment, posting will be accepted but the user has to adjust quantities for the other components (automatically in the system). The input dialog cannot be closed if this modification is not made.

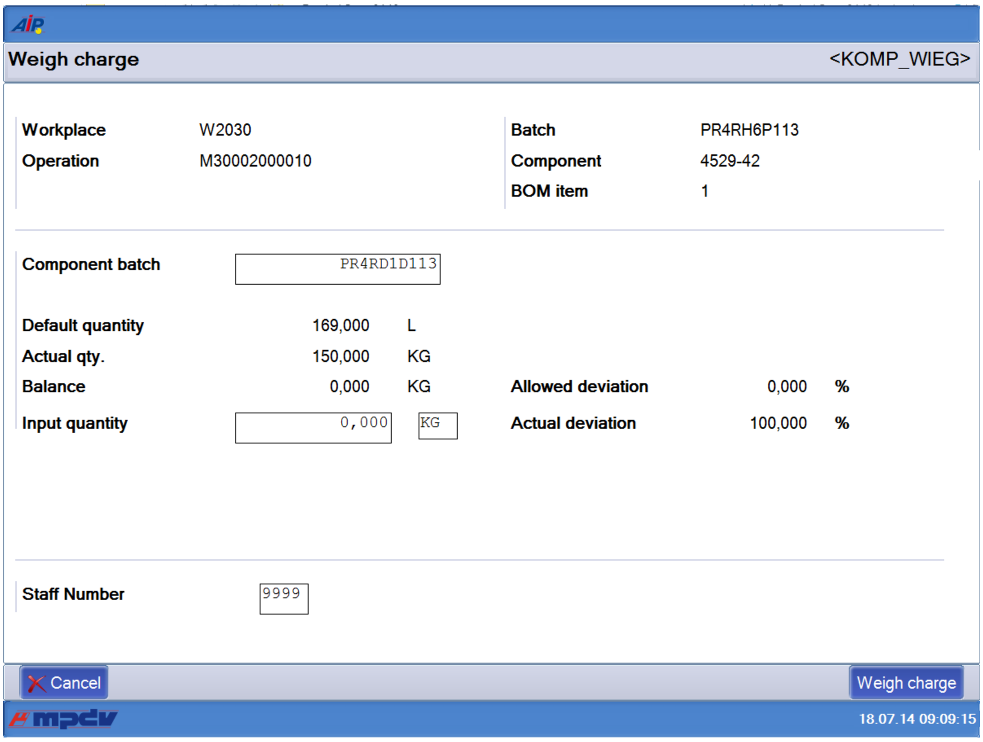
Quantities have to be entered for all input materials included in the component list.

Functions

The paragraphs that follow describe the functions provided in the input dialog to weigh components:

"Weigh charge"

The "weigh charge" function opens the dialog to weigh a selected individual component (KOMP_WIEG).



The current status of target and actual quantity is presented after selecting a component that is to be weighed. The user has to enter a relevant batch for consumption posting in the "component batch" input field. The batch has to be available in HYDRA with the appropriate material and the status "free" and it must have a remaining quantity >=0. The dialog can be closed by entering the weighing quantity and the staff badge number (optional).

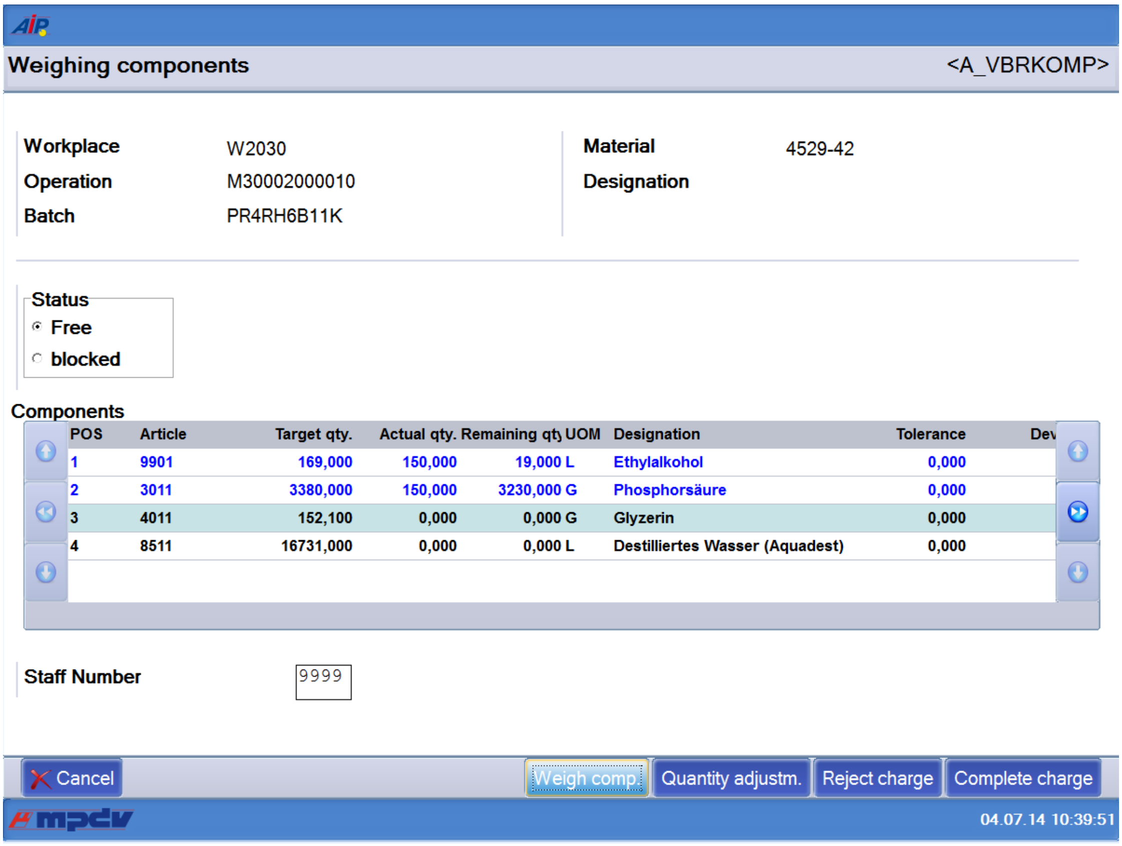
Successful weighing has the following additional effects on the system:

- Indicators are recorded for the component
- The weighed quantity is added to the actual quantity of the component
- Material movements are generated for consumption (261)
- A batch assignment is generated for the batch ⬄ component batch.

- The article of the batch always has to match the article of the component.
- A component may also be weighed several times.
- The amount (stock) of component batches is only reduced if the relevant material type is assigned the "retrograde inventory collection" flag.

Once the weight has been entered, the displayed actual quantity and remaining quantity are updated.

The displayed component requirements are updated in the table once the component has been weighed successfully.



A warning message the user may skip is output if the value of the actual deviation is greater than the one of the target deviation.

"Reject charge" function

Due to the weighing process, it might be the case that an entire batch cannot be used. The "reject charge" function can be used to identify the current charge/batch as "scrap". The material used for this charge is uploaded to ERP and the generated scrap quantity (identified as charge scrap by SYSTEM reason 910) is posted to the order. The batch is generated with the "locked" status and the "scrap" batch class (goods movement 531).

A confirmation prompt the user has to affirm comes up with this function.

Then the original target quantity for each charge is restored and the components are reset. Consequently, the weighing process can be restarted for a new batch.

"Adjust quantity" function

Once the first component has been weighed, the user can apply the "adjust quantity" function to automatically adjust the input quantities of the other components in proportion to the weighing result of the first component and its default quantity. This function can only be used once for each charge.

The function adjusts the target quantities of all components to the weighed quantity of one component. Quantities are adjusted by changing the primary target quantity for each charge of the operation.

However, quantities may only be adjusted if the component is weighed within its tolerances.

"Complete charge" function

Using this function, the charge/batch is completed (generated) and the dialog is closed. However, the charge/batch can only be completed, once all components have been weighed and are within their specified tolerances.

Completed successfully, the charge/batch is generated and transferred as goods movement 101 to ERP. Optionally, the charge/batch is assigned a minimum shelf-life (from the material type of the OP). In addition, the PPS batch from the order is determined and stored as PPS batch in the batch of the charge (optionally).

The quantity of the generated batch results from the input quantity recorded as consumption for each component.

The user may also directly block the batch/charge by selecting a status from the component requirements dialog. By default, the batch is always assigned the status "free".
