

1 Synchronizing File Interfaces

An interface program on an upper-level system (payroll system/ ERP system) assumes the function of preparing the data structures for the transferred files so that they can be processed in batch mode or edited as online transactions.

A handshake logic must be realized between the upper-level system and HYDRA in order to transmit the transfer files so that no data is lost by "overwriting" the transfer files.

Use the following processing method to safely process the files:

1. Rename the interface file into a new file. You do this in Windows NT from the "ren" or "rename" command and in UNIX using the "mv" command.

Please note:

When performing this step, do not use the copy command.

As long as HYDRA is processing the file, it does **not** exist under the documented name.

This ensures that the upper-level system only has access to the file if HYDRA has not yet accessed it (secure handshake).

2. Copy the new file onto the target system.
3. After the new file has been successfully transferred, it must be deleted on the HYDRA server.

A HYD-ZHK module is available on HYDRA with which the automated interfacing can be transferred onto HYDRA. On the PPS system, the files only need to be made available or picked up locally. The files are then actually transferred from and to HYDRA and loaded into the HYDRA database by HYDRA. You can request which technical requirements exactly are needed for this purpose from MPDV project management.
