

1 Graphic Batch Tracing

Usage

The application is only available in the structure described if the modification [battrgextensionselection](#) is enabled.

If you do not use the modification, please refer to this [documentation](#).

Graphic batch tracing is used to represent the relations between the input batches incorporated in a process and the resulting output batches as tree diagram.

Procedure

When using the [graphic batch tracing](#) application, it is especially important to consider which batch links and relations are of interest to the user.

The direction and depth of information are decisive factors.

Possible directions are:

- Going through the batch chain from the beginning to the end
The "consumption" option must be selected if the user is interested in the successive consumption of batches within their process chain.
- Going through the batch chain from the end of the batch chain to the beginning
The user is interested in the development process starting from the output batch and tracing back to the input batches used in the very first process.

Possible levels of information are:

- Direct predecessor/successor level
Only one level or relationship/cross connection of batches may be considered.
- All predecessor/successor levels
All levels or relations of batches may be considered.

Consequently, the right direction and depth of information is important for the analysis and the selection has to be chosen logically (last but not least because of the data volume that might accrue).

- No view or direction (development/consumption) selected

If the direction is not selected specifically, the default system values will be used. Here all input batches are displayed in relation to the output batches they derived from.

- View or direction selected
 - "Origin" checkbox (direction of output batches --> input batches)
For the entered batch all integrated input batches from the preceding level (preceding process) are shown.
If the "initial/final batches" field is still selected, all affected input batches spanning all levels/processes up to the origin are shown.
 - "Consumption" check (direction: input batches --> output batches)
For the entered batch, all output batches resulting for the direct subsequent level are displayed.
If the "determination of initial batches" field is still selected, all affected output batches spanning several levels/processes up to the end or the last level are shown.

The "consumption" option and the "Direct input/output batches" checkbox are set by default in the system.
