

1 Operation Status

Definition

Since order data is entered in relation to operations, the system keeps a status for each individual operation. This status represents the current operation status. Possible statuses are (default values):

 prepared:	The operation has not yet been started
 running:	The operation is currently logged on
 automatically interrupted:	The operation is currently logged on, but was interrupted automatically by the shift automation at the end of the shift
 interrupted	The operation has been interrupted.
 finished:	The operation has been logged off.

The operation status can be configured to a defined extent (HYDRA Customizing). Please note in this context that an operation status with exactly one control indicator is configured for each order type (exception: status with control indicator “S” may exist several times).

Please note for the “automatically interrupted” status (control indicator “F”)

This status is set automatically by the shift automation for a running operation at the end of the shift. When the next shift starts, the status is again set to the status assigned to the control indicator “running” (“L”). If this status is shown this might be due to:

- 1) No shift is defined
- 2) The terminal has sent the end of the shift, but no beginning of the shift, e.g. as it was fully switched off or was booting

Orders cannot be posted for an operation assigned to the “automatically interrupted” status.
