

1 Application-relevant customizing in SAP

Maintain control recipe destination

For each HYDRA system connected to SAP PP-PI a control recipe destination has to be maintained. In a first step the control recipe destination is linked with the RFC destination created in SAP transaction SM59. In further steps the process instructions have to be assigned.

To maintain the control recipe destination SAP transaction O10C is used (path with transaction SPRO: *Production Planning for Process Industries → Process Management → Decentralized Process Management → Define and Set Up Control Recipe Destinations*). It is important to maintain the control recipe destination of type “2”, as this is the type supported by the HYDRA PP-PI-PCS implementation.

Maintain control recipe destination in master recipe

The control recipe destination created in transaction O10C has to be assigned to a specific phase in the master recipe. By assigning control recipe destination that phase is relevant for downloading to HYDRA when the control recipe is created.

In most cases the operations in the master recipe are not relevant for HYDRA but only the phases.

Define background job for sending control recipe

In this step a background job for sending control recipes in the SAP client is defined. For each job, the following settings have to be made (SAP transaction SM36):

Start date of the job

One of the following options can be used:

The job should be started each time a new control recipe has been created in your client:

After event SAP_NEW_CONTROL_RECIPES

Event parameter <client>

Periodic job

The job should run periodically at certain intervals (option **Date/Time** with the time interval stored as a **period value**).

Steps to be carried out

The job should start the **ABAP report program** RCOCB006.

Define background job for sending process messages

In this step, a background job for sending process messages automatically is defined. This is necessary to process the process messages with confirmations sent from HYDRA to SAP within SAP and to post the data to the process order. To define the job SAP transaction SM36 is used.

Types of sending

The following options are available for background jobs:

Cross-plant sending

You use program RCOCB002 for this.

Plant-specific sending

You use program RCOCB004 for this. You specify the plant of the messages to be selected in a selection variant.

The system processes all messages that have status:

- Created
- To be resubmitted
- To be resubmitted with warning

Start date of the job

In certain time intervals

After the event SAP_NEW_PROCESS_MESSAGES, this means, every time new messages are available

For cross-plant sending, you specify the client as the event parameter.

For plant-specific sending, you specify the client and plant as the event parameters.

Define production scheduling profiles

In the production scheduling profile it is defined, if the control recipe is created automatically when releasing the process order. Production scheduling profiles can be assigned to a

- material (work scheduling screen in material master)
- production scheduler (Customizing)

The assignment to the material has a higher priority.

The production scheduling profile is copied to the production order or process order on order creation.
