1 Overview of Alternative Methods for Data Collection

Purpose

The component alternative data collection methods provides basic functions that allow you to execute posting rules deviating from the ones provided in the standard delivery or that make it possible to enter and post other order-related performances/activities other than quantities and times.

Examples of application scenarios

- Orders have very few units but a very long run time (e.g. 3 units, duration 4 weeks; estimated net time approx. 40 hrs).

The customer would like to log the OP on and off in order to identify the OP's status. However, there are many active OPs in the workshop, yet that does not reveal which one is being actively processed.

For example, the time used is entered once a week by the supervisor. In addition, it would also be a nice option if, regardless of the time used, it were possible to enter the remaining working time (this example can also be transferred very well to a maintenance solution).

- Furthermore, in many projects the task is to "simply" enter a specific value and upload it to the higher-level system without this involving any other processing operations in HYDRA.
- Sometimes what is required is that the relevant number of employees involved must be posted, rather than logging people on and off individually. Labor utilization is then the result of multiplying the duration recorded by this number of persons. (This often also involves the works council, which makes this requirement in these kinds of projects particularly important.)
- Often, what is required is that additional data is entered beyond the typical data entry variables such as quantities and times. Example: Power consumption

Implementation notes

You use the function package if:

- You have activities (operations) or workplaces, where time use cannot be determined by calculating the difference between operation logon and logoff, but instead must be entered separately.
- For a specific order, you want to enter and post other order/operation-related activities other than quantities produced and times used.

Integration

The basic functions included in this component are used to enter and post activities from the server. They do not provide any visual functions. The modifications needed for this at the shop floor client (e.g. terminal) must be considered separately.

If additional activities entered should also be uploaded to a higher-level system, then you have to configure the interface separately. Additionally entered activities are not available for evaluation in MOC at this time.

Features

Basic functions for processing different data collection methods in the BDE environment:

- Time event-related entry and based on it, the calculation of the time to be posted.
- Time-ticket-based entries
- Combination of the two entry types
- Automatic calculation from other variables, e.g. calculation of labor utilization from duration x explicitly entered number of persons
- Order-related posting of consumption data entered (e.g. consumption of power, water, energy, supplies ...)

Please note: Adding and coordinating the specific requirements and implementing them are considered a customized HYDRA service (a service subject to an added charge).
