

1 Shift Automatism

Usage

The shift automatism activates functions that facilitate data collection as well as operability by enabling the terminal to automatically recognize shift start and shift end for the workplaces/machines assigned to it.

Integration

An active shift automatism has an effect on

- the generation of order-related postings (log records) in shop floor data collection (BDE).
- the generation of machine-related postings (log records) in machine data collection (MDE).
- the test times in CAQ.

Prerequisite

The functions described below are only active on a machine/a workplace meeting the following requirements:

- The machine/workplace is configured as a so-called "Single workplace".
- The machine/workplace is attributed to a terminal configured with operation mode "MDE".

These functions are not available at workplaces configured as group workplaces.

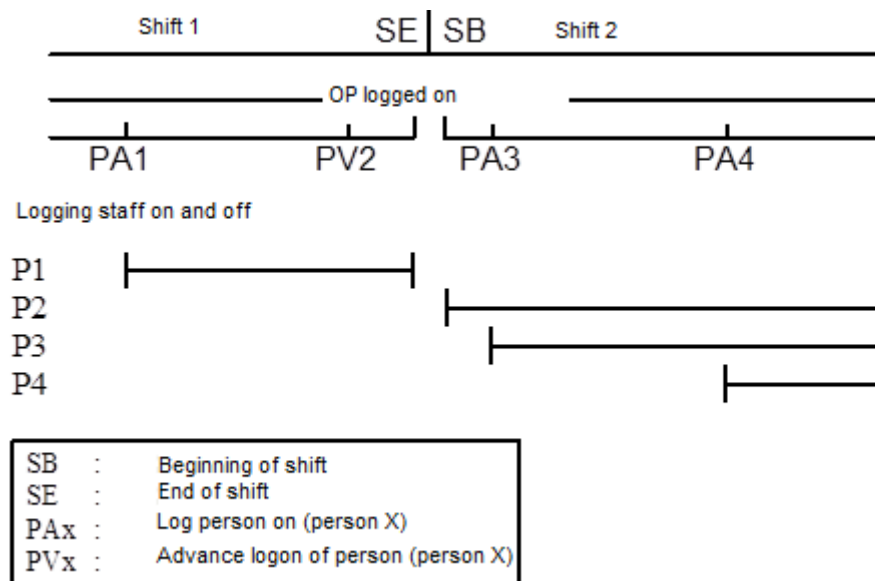

In order to ensure processing, the terminal software must be running!

Features

The following actions are initiated upon an automatic shift change:

- at the end of shift according to the BDE shift calendar, the running OP is interrupted automatically;
- at the next shift start according to the BDE shift calendar, this OP is logged on again automatically.
- Persons may perform an "Advance logon" at a terminal by a specific deadline prior to shift start (acc. to BDE shift calendar). At the next shift start, the terminal will then log these persons on to the operation. The time range is determined by the *Waiting period for advance logon of staff* option of the terminal configuration.

The chart below shows the time sequence of logons and logoffs upon a shift change.

Description of sequence:

1. An OP was logged on in the current shift 1 and is also to be continued in the following shift 2.
2. Person 1 logs on to the workplace.
3. Person 2 arrives shortly before the end of shift and logs onto the workplace. Since logon takes place within the specified 30 minutes of advance logon time, the terminal recognizes an advance logon.
4. At the end of shift, the running OP is interrupted automatically and all persons logged on are logged off.
5. At the start of the next shift, the previously interrupted OP is logged on again. In addition, the persons with advance logon are logged on.

Since data collection at the terminals must not be interrupted and not all terminals may send all postings simultaneously at the end of shift, the log records are buffered. Subsequently, the buffer is transferred in brief intervals to the server. This process depends on the number of machines defined at a terminal. Postings made during this period are buffered in turn.
