

1 Behavior Depending on the Transfer Types

Initial download behavior

An initial download of the order and operation data will only take place when the complete system is commissioned and a first database is to be created in HYDRA. In addition, also other scenarios are possible by which the entire operations base will be replaced.

During an initial download all operations from SAP will be transferred that have at least the status "released" or that are not technically completed yet. This means that also (end) confirmed operations will be transferred but not imported in HYDRA.

When the initial download is received, the current operations data base in HYDRA will be deleted and be replaced by the new operations data. The current data will immediately be available.

An initial download will not only delete the order base existing in HYDRA but also all current times and quantities entered for orders and/or transactions.

In addition, all operations that are being executed will not be deleted. This means that they must be interrupted and/or terminated manually in HYDRA.

Conclusion: Any initial download during the operation of HYDRA must be used with greatest care and it would be useful to contact the MPDV Support beforehand.

For security reasons, the initial download function needs to be enabled explicitly as of the below-mentioned program version. Activation is performed by an INI configuration.

.\lib\b_anr.dll

V8.1.1.326

Delta download behavior

A delta download creates new operations in HYDRA that will then be added to the database. Another function of the delta download is the modification of already transferred operations. Modifications of operations with the status "Running", "Finished" or "Deleted" are not allowed by the HYDRA default settings.

CUSTOMIZING information: Modifications of the operations depend on whether the flag "alterable order data" is set for the corresponding status in the status configuration.

If an operation cannot be modified to ensure the consistency in HYDRA (in general for running operations), this will be logged in HYDRA and be saved for error tracking purposes.

The basis for the delta download in SAP is the database table ORDCOM.

Deletion download behavior

A deletion download deletes those operations that are no longer necessary in the production process from the HYDRA database.

As with the modifications, the deletion result depends on the operation's status. Operations identified as "Running", "Interrupted", "Finished" or "Deleted", will not be deleted.

Moreover, the confirmation number (CONF_NO) will be checked to identify the orders via order, sequence and transaction. This prevents any accidental deletion of orders that are seemingly the same but which have different confirmation numbers.

Behavior when re-importing master data in SAP

When master data for an existing and released order that has already been transferred to HYDRA are re-imported in SAP this impacts also the interface to HYDRA.

When master data are re-imported, SAP will assign new confirmation numbers for the individual operations even though the order and operation numbers won't change. These are then transferred together with the next delta download to HYDRA. The confirmation/upload number will then be updated in HYDRA.

The update will also be made when the current status is "Running". In this case, however, ONLY the confirmation/upload no. will be changed and all other data (order quantity, scheduling, etc.) will not be updated.

Behavior during the technical completion in SAP

If an order is technically completed in SAP this will lead to a deletion download at the interface. This means that the order data in HYDRA will be deleted.
