

1 Access Control

Summary

The access control (HYDRA-ZKS) module has been designed to control accesses/entrances (e.g. doors, gates) as well as to check and record access attempts at entrances by HYDRA terminals.

[Accesses](#) are entrances, exits or passages that are to be monitored. When accesses are configured, they are assigned to a terminal and their properties are configured.

Accesses, which are supposed to get the same access authorizations, are summarized to [access groups](#) to allow for a simple editing and handling of access authorizations.

People receive [badges](#) for access control purposes. Their validity may be restricted with respect to time. The licenses entitled “enhanced access control” (ZKS-EZK) and “visitor badge management” (ZKS-BAV) allow for replacement badges or visitor badges to be created and handed out.

[Access time models](#) are created for accesses and people who are allowed to enter. These access time models include the [access periods](#) of week days and [public holidays](#) when accesses are allowed.

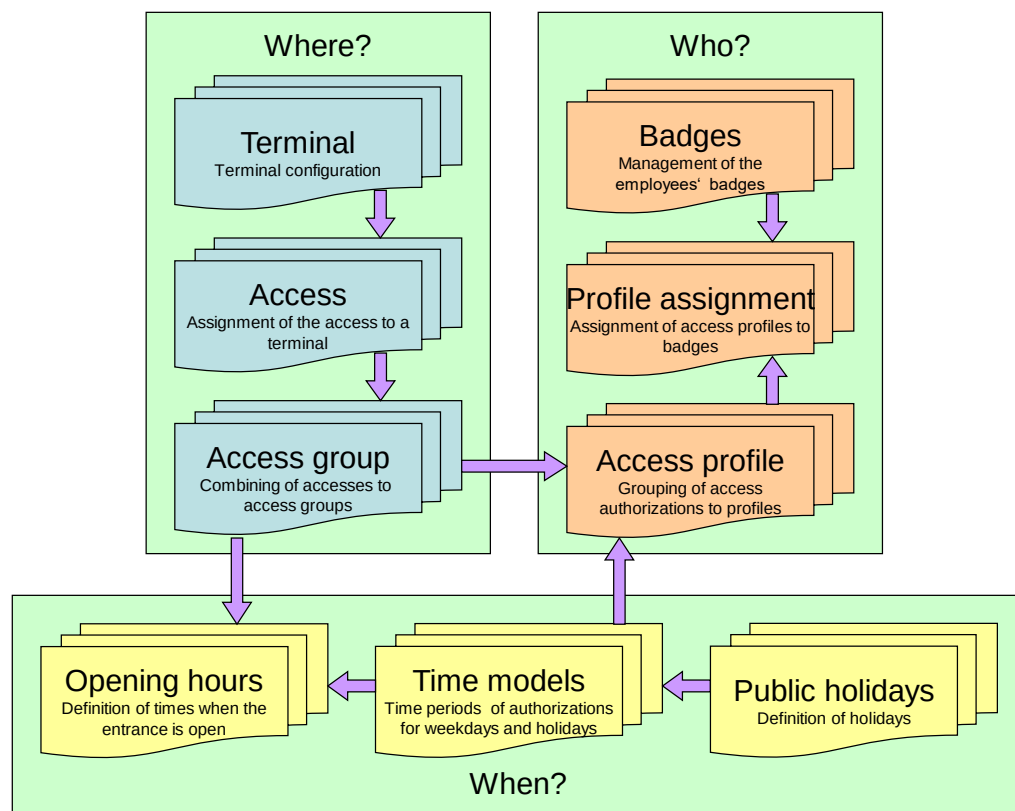

[Access profiles](#) are created to simplify editing of access authorizations. These profiles are assigned to all people or badges that are to receive the same access authorizations.

[Access authorizations](#) are defined in access profiles by assigning access groups including the corresponding access time models.

The [opening hours](#) of accesses are defined by assigning an access time model to individual access groups. These entrances may be opened during the access time periods that result from this procedure. These opening times may also control the recording of accesses and access attempts as well as if entries can be opened permanently.

The access functions at the terminal are available even if the connection to the HYDRA server breaks down. In this case, access authorizations are based on the situation that existed before the connection broke down.

Configuration of Access Control

This diagram explains the connections to HYDRA-ZKS configurations.
