

1 PRA Profile

Summary

Menu	Operating facilities management → Status analyses → RPA profile
Transaction code	rpap
Function authorization	rpap

Usage

The RPA profile provides status information for a specific period of time and a certain number of workplaces. In it, the status of resource performance accounts that were assigned in a previous step are consolidated and displayed by shift.

Selection criteria

The application provides the following selection criteria:

Workplace

Search by machine/ by workplace You can also run a search using wildcards.

Group

Search by workplaces/ machines that are assigned to the group that was entered. The selection is made using the field Group in the workplace/ machine configuration. You can also run a search using wildcards.

Cost center

Search by workplaces/ machines that are assigned to the cost center that was entered. You can also run a search using wildcards.

Company

Search by workplaces/ machines that are assigned to the company that was entered. You can also run a search using wildcards.

Responsibility area

This selection criterion references the responsibility area in the machine master data. Keep in mind that only machines are displayed that the user has also assigned responsibility areas to.

Report group

This selection criterion references the report groups. All machines or workplaces are displayed that are assigned to the selected report group.

Short name

This selection criterion references the short name of the machines in the master data. All of the machines or workplaces are displayed that match the string that was entered. You can also run a search using wildcards.

Designation

This field references the designation (in HYDRA: comment) used for the machines and workplaces in the machine master data. At the bottom, only those machines are displayed that are identical to the string that was entered. There is also the option to use wild cards (placeholders *) in this field.

Inclusive status for RPA 11

Accounts for the status for RPA 11 (usually, this is the "Production" status).

Date

The period of time from which data should be selected.

When selecting via shift(s), the shift date is evaluated, while when selecting by time the selection is based on the start date. Please keep in mind that a selection by shift is only supported for BDE and MDE data, not for WRM data.

Shift(s)/ time

Selection by shift (only BDE and MDE events) or by time period. If no shift has been selected, all shifts are considered.

The two times each refer to the start or to the end of the date periods listed above.

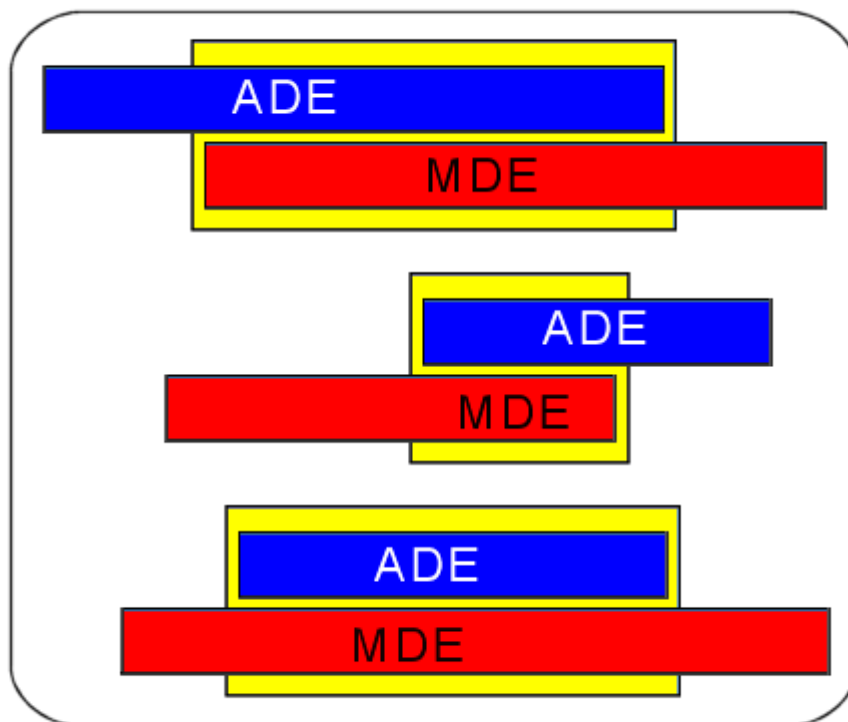

Order/ article

When you choose the option "Order", you must enter an order or an article.

For this kind of evaluation type, only the finished BDE postings are considered. If the order is currently still running on the machine, the time period between the last log on and now is not taken into account. As such, it is by all means possible that there are differences between the machine evaluation and the order-related evaluation. Only BDE postings are taken into account that have started during the evaluation period. If necessary, the selection period must be selected so that the BDE postings that are to be taken into account are within this selection period. For this order-related evaluation, MPDV recommends the shift-related selection option.

The following illustration shows an example of an overlapping of BDE and MDE postings. The BDE postings take priority in this evaluation type. The yellow areas illustrate the results of this evaluation. MDE quantities and durations are calculated on a pro rata basis to achieve the result.

If orders are logged on in parallel at the machine, for this evaluation type, the full machine time (yellow area) and quantity is assigned to each order. The fact that orders are run in parallel will not result in a proportionate calculation.

Resource type/ resource

When choosing the option "Resource", a resource must be entered.

For this kind of evaluation type, here again only the finished postings are considered. For this evaluation type, only the resource postings take priority. The principle is the same as when running an evaluation by order.

Additional selection notes

Long term data

If the selection period exceeds the period for the online data area, the system applies the implicit solution and selects the medium-term data area as well. Therefore, there is no need for an explicit activation in order to be able to access the medium-term data set.

Determining a shift-adjusted quantity

This option known from MDE 7.2 is set by default in MOC. What this means is that postings that were generated as a result of a shift change are not considered when determining the quantity. All that is accounted for here is the exact moment when a machine status was set. If this moment is outside of the evaluation interval, in this case the output will be 0.

Overview of detail application

Shift date/ shift/ calendar week/ year

The durations in the resource performance accounts are displayed in groups by shift (i.e. shift date/ shift number).

Calendar week and year are displayed as a possible sorting/ grouping criterion. The calendar week and the year match the shift date.

RPA/ abbreviation/ designation

When delivered from the factory, the durations set for the resource performance accounts 1-10 are listed in the pool of columns. They are stored there with their abbreviation and can be shown as needed.

Duration

Time duration in which the status was created/ set within the evaluation period.

Quantity

Number of times that the status was created/ set within the evaluation period.

Duration detail application

In the duration detail application, the resource performance account durations are displayed in the form of a stacked bar chart. They are displayed in chronological form (X axis) or accumulated to shift date (Y axis). The color code for each of the resource performance accounts is in accordance with the standard definitions.

Quantity detail application

In the quantity detail application, the number of statuses for the selected machines are displayed in the form of a stacked bar chart, broken down by RPA. They are displayed in chronological form (X axis) or accumulated to shift date (Y axis). The color code for each of the resource performance accounts is in accordance with the standard definitions.
