

1 Status of Consumption Correlation

Overview

Menu	Resource management → Resource analysis → Status of consumption correlation
Transaction code	concorsta
Function authorization	concorsta

This document describes the application "Status of consumption correlation" in the Manufacturing Operation Center (MOC).

Application

The application "Status of consumption correlation" is new. The status of consumption correlation graphically shows the energy consumption in relation to the recorded statuses of workplaces/machines. You can present energy consumption in connection with the accrued information on statuses. This way, it is e.g. possible to identify the energy consumption during the setup or a disturbance.

Energy documents are assigned to the statuses by time and selection.

Please note:

The application only shows completed status documents.

Selection criteria

Reference

Selection of resources using the resource list

Date from / until

Selection of a period for consumption correlation

Workplace

Selection of workplace using the workplaces dialog

Group from / to

Selection based on a group. Selection by drop-down list

Report group

Selection based on a report group. Selection by drop-down list

Automatic counter assignment

If this option is checked, HYDRA identifies automatically the relevant energy counters following the counter to machine assignment.

Detail application status of consumption correlation

The detail application includes two sections. The upper part shows the status of machines/workplaces, the lower section displays the consumption.

The statuses matching the above mentioned selection criteria (period from/to, workplace, group/report group) are displayed as individual bars in the detail application (1 row for each workplace/machine).

The user can select the displayed status log records (multiple selection is possible by using the Ctrl key). The resulting time slice/s is/are used for presenting the consumption.

The lower section of the detail application shows two sections with different information for each selected consumption meter.

Section 1:

This section shows the result of the correlation: The periods result from the selected order and multiple selection of order bars.

Section 2:

The consumption documents matching the selected consumption meter and period entered in the selection panel are shown. However, they are not displayed as complete document but rather as averaged point (average power in the document). This refers to the load profile of the consumption resource.
