

1 Status Class Report

Summary

Menu	Operating facilities management → Status analyses → Status class report
Transaction code	stclrp
Function authorization	stclrp

Usage

The evaluation provides status information for a specific period of time and a certain number of workplaces. In it, the statuses are consolidated into status classes that were assigned in a previous step. The application provides the user with the ability to run an analysis of the booked status classes.

Selection criteria

The application provides the following selection criteria:

Workplace

Search by machine/ by workplace. You can run a search using wildcards.

Group

Search by workplaces/ machines that are assigned to the group that was entered. The selection is made using the field Group in the workplace/ machine configuration. You can run a search using wildcards.

Cost center

Search by workplaces/ machines that are assigned to the cost center that was entered. You can run a search using wildcards.

Company

Search by workplaces/ machines that are assigned to the company that was entered. You can run a search using wildcards.

Responsibility area

This selection criterion references the responsibility area in the machine master data. Keep in mind that only machines are displayed that the user has also assigned responsibility areas to.

Report group

This selection criterion references the report groups. All machines or workplaces are displayed that are assigned to the selected report group.

Short designation

This selection criterion references the short name of the machines in the master data. All of the machines or workplaces are displayed that match the string that was entered. You can also run a search using wildcards.

Designation

This selection criterion references the name of the machines and workplaces in the machine's master data. At the bottom, only those machines are displayed that are identical to the string that was entered. You can also run a search using wildcards (placeholders *) in this field.

Date

The period of time from which data should be selected.

When selecting via shift(s), the shift date is evaluated, while when selecting by time the selection is based on the start date. Please keep in mind that a selection by shift is only supported for BDE and MDE data, not for WRM data.

Shift(s)/ time

Selection by shift (only BDE and MDE events) or by time period. If no shift has been selected, all shifts are considered.

The two times each refer to the start or to the end of the date periods listed above.

Order/ article

When you choose the option "Order", you must enter an order or an article.

For this kind of evaluation type, only the finished BDE postings are considered. If the order is currently still running on the machine, the time period between the last logon and now is not taken into account. As such, it is by all means possible that there are differences between the machine evaluation and the order-related evaluation. Only BDE postings are taken into account that have started during the evaluation period. If necessary, the selection period must be selected so that the BDE postings that are to be taken into account are within this selection period. For this order-related evaluation, MPDV recommends the shift-related selection option.

The following illustration shows an example of an overlapping of BDE and MDE postings. The BDE postings take priority in this evaluation type. The yellow areas illustrate the results of this evaluation. MDE quantities and durations are calculated on a pro rata basis to achieve the result.

If orders are logged on in parallel at the machine, for this evaluation type, the full machine time (yellow area) and quantity is assigned to each order. The fact that orders are run in parallel will not result in a proportionate calculation.

Resource type/ resource

When choosing the option "Resource", a resource must be entered.

For this kind of evaluation type, here again only the finished postings are considered. For this evaluation type, only the resource postings take priority. The principle is the same as when running an evaluation by order.

Additional selection notes

Long term data

If the selection period exceeds the period for the online data area, the system applies the implicit solution and selects the medium-term data area as well. Therefore, there is no need for an explicit activation in order to be able to access the medium-term data set.

Determining a shift-adjusted quantity

This option known from MDE 7.2 is set by default in MOC. What this means is that postings that were generated as a result of a shift change are not considered when determining the quantity. All that is accounted for here is the exact moment when a machine status was set. If this moment is outside of the evaluation interval, in this case the output will be 0.

Status class report detail application

Tabular presentation of the status class reports

Status class

Status class number

Abbreviation

Abbreviation of the status class

Designation

Description of the status class

Duration

Total time of all statuses within the evaluation period, accumulated to status classes.

%

Proportion of the total duration of the status classes.

Quantity

Total number of all statuses within the evaluation period, accumulated to status classes.

%

Proportion of the number of statuses to the total number of all statuses.

Status class hit list (durations) detail application

Displayed in a bar chart in the status class hit list (durations) detail application are the durations posted to status classes. Displayed here are the status classes that were highlighted in the tabular detail application status class report. The red bars are shown in descending order by duration.

Status class hit list (quantities) detail application

Displayed in a bar chart in the status class hit list (quantities) detail application are the number of status classes. Displayed here are the status classes that were highlighted in the tabular detail application status class report. The red bars are shown in descending order by quantity.
