

1 Batch Object

Definition

A batch is a homogeneous quantity of a material of the same quality that is located at one and the same place at one point in time.

A batch's granulation and/or the batch size depend on the corresponding material and is in general geared to containers or transport units. To track individual parts, the batch size 1 is selected.

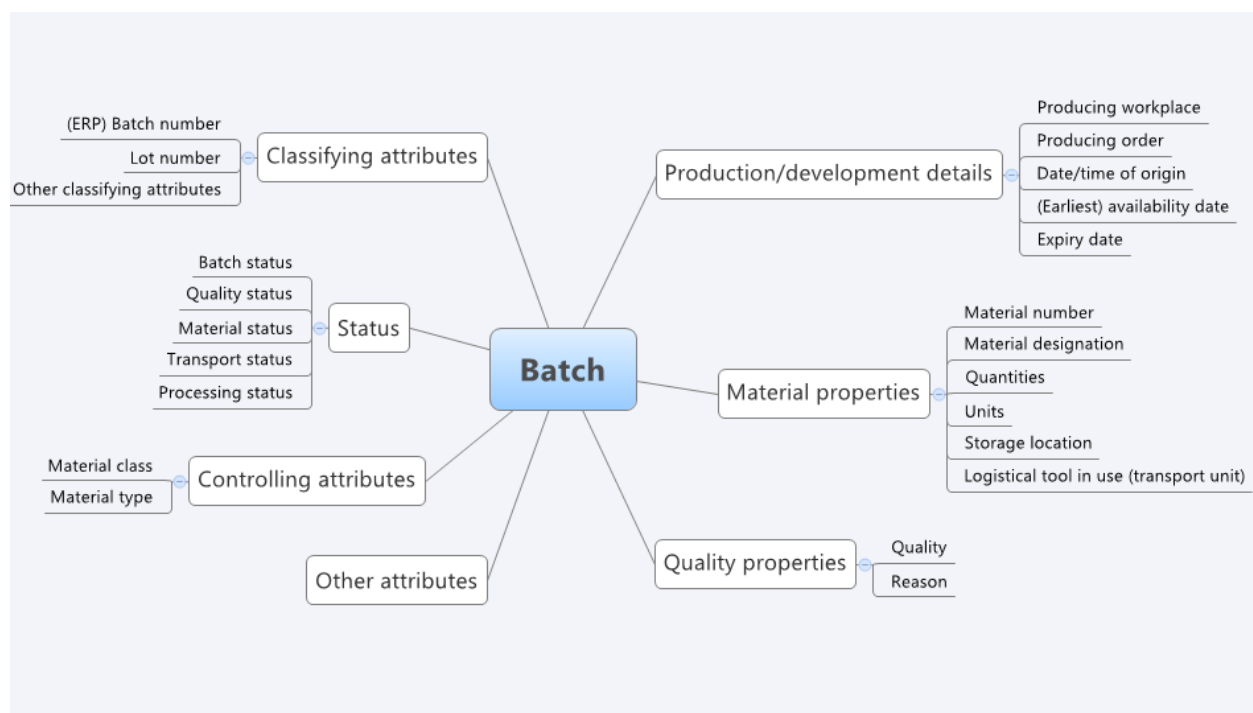

Usage

Batches are used to assess, to control and to evaluate by tracking material flows in the production of a company.

They can also be used to precisely group and identify quantities of a material in case of external sending-ahead (e.g. transport to the customer).

Structure

Each batch is identified by a unique batch identification that is either assigned by an upstream system (mostly an ERP system) or by the system itself that is administered in the system; and which is physically added to the batch in form of a label, for example. In addition to the batch number, the batch object is structured as follows:

Integration

Batches can be posted to a material buffer in order to determine and to monitor the inventories in production.

A [material type](#) is assigned to each batch that includes essential control indicators depending on the batch's situation (input or output batch).

To enter logical transport resources a [transport unit](#) can be assigned to each batch.

Batches can be reserved for an order/ operation.
